Governments often redistribute by subsidizing consumption.

Examples: SNAP (food stamps), childcare subsidies, public transit discounts.

Subsidy programs in practice are often nonlinear: marginal subsidy depends on total quantity.

Examples: capped vouchers, co-pays, public options.

This paper: we characterize the optimal nonlinear subsidy program for redistribution.

Key questions:

- #1. When should a social planner subsidize consumption?
- **#2.** How are subsidies optimally designed?

Our approach: we pose and solve the mechanism design problem for the optimal subsidy.

Model Scope Characterization Derivation Positive Correlation Discussion Extensions Conclusion Appendix

Key Tradeoff

The optimal subsidy program trades off:

- #1. screening, distorting consumption to redirect surplus to high-need consumers, versus
- #2. heterogeneous outside options, consumers can buy from private market.

Model Scope Characterization Derivation Positive Confetation Discussion Extensions Conclusion Appendix

Key Tradeoff

The optimal subsidy program trades off:

- #1. screening, distorting consumption to redirect surplus to high-need consumers, versus
- #2. heterogeneous outside options, consumers can buy from private market.

Heterogeneous outside options are empirically relevant, e.g.,

- public housing (van Dijk, 2019; Waldinger, 2021),
- education (Akbarpour, Kapor, Neilson, van Dijk & Zimmerman, 2022; Kapor, Karnani & Neilson, 2024),
- healthcare (Li, 2017; Heim, Lurie, Mullen & Simon, 2021),
- SNAP (Haider, Jacknowitz & Schoeni, 2003; Ko & Moffitt, 2024; Rafkin, Solomon & Soltas, 2024).

Heterogeneous outside options lead to lower-bound constraints in the mechanism design problem.

Model Scope Characterization Derivation Positive Correlation Discussion Extensions Conclusion Appendix #2

We provide an explicit characterization of:

- (a) when the social planner strictly benefits from subsidizing consumption, and
- (b) how the optimal subsidy depends on quantity consumed.

We provide an explicit characterization of:

- (a) when the social planner strictly benefits from subsidizing consumption, and
- (b) how the optimal subsidy depends on quantity consumed.

Key determinant of subsidy design: correlation between demand (type θ) and need (welfare weight ω).

Model Scope Characterization Derivation Positive Correlation Discussion Extensions Conclusion Appendix

Setup

Consumers:

- ▶ There is a unit mass of risk-neutral consumers in market for a divisible, homogeneous good.
- lacktriangle Consumers differ in type $\theta \in [\underline{\theta}, \overline{\theta}]$ with $\underline{\theta} \geq 0$, and $\theta \sim F$, continuous with density f > 0.
- ► Each consumer derives utility $\theta v(q) t$ from quantity $q \in [0, A]$ given payment t.

$$v:[\mathsf{O},\mathsf{A}] o \mathbb{R}$$
 is differentiable with $v'>\mathsf{O}$, $v''<\mathsf{O}$ and $\lim_{q\to \mathsf{O}} v'(q)=+\infty$.

Setup

Consumers:

- There is a unit mass of risk-neutral consumers in market for a divisible, homogeneous good.
- ► Consumers differ in type $\theta \in [\underline{\theta}, \overline{\theta}]$ with $\underline{\theta} \geq 0$, and $\theta \sim F$, continuous with density f > 0.
- ► Each consumer derives utility $\theta v(q) t$ from quantity $q \in [0, A]$ given payment t.

$$extstyle v: [extstyle 0, extstyle A] o \mathbb{R}$$
 is differentiable with $extstyle v' > 0$, $extstyle v'' < 0$ and $\lim_{q o 0} v'(q) = +\infty$.

Producers:

ightharpoonup The good is produced competitively at a constant marginal cost per unit, c > 0.

Setup

Consumers:

- ▶ There is a unit mass of risk-neutral consumers in market for a divisible, homogeneous good.
- lacktriangle Consumers differ in type $\theta \in [\underline{\theta}, \overline{\theta}]$ with $\underline{\theta} \geq 0$, and $\theta \sim F$, continuous with density f > 0.
- ► Each consumer derives utility $\theta v(q) t$ from quantity $q \in [0, A]$ given payment t.

$$v:[\mathsf{O},\mathsf{A}] o \mathbb{R}$$
 is differentiable with $v'>\mathsf{O}$, $v''<\mathsf{O}$ and $\lim_{q o \mathsf{O}} v'(q) = +\infty$.

Producers:

ightharpoonup The good is produced competitively at a constant marginal cost per unit, c > 0.

Extensions (not today): equilibrium effects, observable characteristics, product choice and eligibility.

Laissez-Faire Equilibrium

- ▶ Perfectly competitive private market \sim laissez-faire price $p^{LF} = c$ per unit.
- Each consumer solves

$$U^{\mathsf{LF}}(\theta) := \max_{q \in [\mathsf{O},\mathsf{A}]} \left[\theta v(q) - cq \right].$$

v is strictly concave → unique maximizer:

$$q^{\mathsf{LF}}(\theta) = (\mathbf{v}')^{-1}\left(\frac{\mathsf{c}}{\theta}\right) = D(\mathsf{c},\theta).$$

Social planner costlessly contracts with firms and sells units at a subsidized payment schedule $P^{\sigma}(q)$.

 $\sim \Sigma(q) = cq - P^{\sigma}(q)$ is the total subsidy as a function of q, and $\sigma(q) = \Sigma'(q)$ is the marginal subsidy.

Social planner costlessly contracts with firms and sells units at a subsidized payment schedule $P^{\sigma}(q)$.

 $\sim \Sigma(q) = cq - P^{\sigma}(q)$ is the total subsidy as a function of q, and $\sigma(q) = \Sigma'(q)$ is the marginal subsidy.

Key assumptions:

1. Each consumer can top up his consumption of the good, allowing him to purchase additional units in the private market at price c,

$$\rightarrow \sigma(q) \geq 0$$
 for all q .

Social planner costlessly contracts with firms and sells units at a subsidized payment schedule $P^{\sigma}(q)$.

 $ightharpoonup \Sigma(q) = cq - extstyle P^{\sigma}(q)$ is the total subsidy as a function of q, and $\sigma(q) = \Sigma'(q)$ is the marginal subsidy.

Key assumptions:

1. Each consumer can top up his consumption of the good, allowing him to purchase additional units in the private market at price c,

$$\sim \sigma(q) \geq 0$$
 for all q .

2. The social planner can subsidize but not make lump-sum cash transfers,

$$\rightsquigarrow P^{\sigma}(q) \geq 0$$
 for all q .

Social planner costlessly contracts with firms and sells units at a subsidized payment schedule $P^{\sigma}(q)$.

 $\sim \Sigma(q) = cq - P^{\sigma}(q)$ is the total subsidy as a function of q, and $\sigma(q) = \Sigma'(q)$ is the marginal subsidy.

Key assumptions:

1. Each consumer can top up his consumption of the good, allowing him to purchase additional units in the private market at price c,

$$\sim \sigma(q) \geq 0$$
 for all q .

2. The social planner can subsidize but not make lump-sum cash transfers,

$$\sim P^{\sigma}(q) \geq 0$$
 for all q .

 $\underline{\mathsf{Implementation}} \text{: Consumer } \theta \text{ solves } \boldsymbol{U}^{\sigma}(\theta) := \max_{\boldsymbol{q}} [\theta \boldsymbol{v}(\boldsymbol{q}) - \boldsymbol{P}^{\sigma}(\boldsymbol{q})] \text{, leading to subsidized demand } \boldsymbol{q}^{\sigma}(\theta).$

The social planner seeks to maximize weighted total surplus.

▶ Consumer surplus: social planner assigns a welfare weight $\omega(\theta) := \mathbf{E}[\omega|\theta]$ to consumer type θ .

 $\, \leadsto \, \omega(\theta) \text{:}\,$ expected social value of giving consumer θ one unit of money.

The social planner seeks to maximize weighted total surplus.

- ▶ Consumer surplus: social planner assigns a welfare weight $\omega(\theta) := \mathbf{E}[\omega|\theta]$ to consumer type θ .
 - \sim $\omega(\theta)$: expected social value of giving consumer θ one unit of money.
- ▶ Total costs: social planner assigns a welfare weight of $\alpha \in \mathbb{R}_+$ to total costs.
 - captures opportunity cost of subsidy spending (cf. other redistributive programs, tax cuts).

The social planner seeks to maximize weighted total surplus.

- lacktriangle Consumer surplus: social planner assigns a welfare weight $\omega(\theta) := \mathbf{E}[\omega|\theta]$ to consumer type θ .
 - $\rightarrow \omega(\theta)$: expected social value of giving consumer θ one unit of money.
- ▶ Total costs: social planner assigns a welfare weight of $\alpha \in \mathbb{R}_+$ to total costs.
 - captures opportunity cost of subsidy spending (cf. other redistributive programs, tax cuts).
- \sim Objective:

$$\max_{\boldsymbol{P}^{\sigma}(\boldsymbol{q}) \geq 0 \text{ s.t. } \sigma(\boldsymbol{q}) \geq 0} \int_{\theta} \left[\omega(\theta) \boldsymbol{U}^{\sigma}(\theta) - \alpha \Sigma(\boldsymbol{q}^{\sigma}(\theta)) \right] d\boldsymbol{F}(\theta)$$

The social planner seeks to maximize weighted total surplus.

- ▶ Consumer surplus: social planner assigns a welfare weight $\omega(\theta) := \mathbf{E}[\omega|\theta]$ to consumer type θ .
 - $\sim \omega(\theta)$: expected social value of giving consumer θ one unit of money.
- ▶ Total costs: social planner assigns a welfare weight of $\alpha \in \mathbb{R}_+$ to total costs.
 - captures opportunity cost of subsidy spending (cf. other redistributive programs, tax cuts).

$$\sim$$
 Objective:

$$\max_{P^{\sigma}(q) \geq 0 \text{ s.t. } \sigma(q) \geq 0} \int_{\theta} \left[\omega(\theta) U^{\sigma}(\theta) - \alpha \Sigma(q^{\sigma}(\theta)) \right] dF(\theta)$$

Remarks:

- ▶ If ω(θ) > α, social planner would want to transfer a dollar to type θ.
- If $\mathbf{E}_{\theta}[\omega(\theta)] > \alpha$, social planner would want to make a lump-sum cash transfer to all consumers.

Correlation Assumption

Two baseline cases:

- "Negative Correlation": $\omega(\theta)$ is decreasing in θ .
 - high-demand consumers tend to have lower need for redistribution.
 - e.g., food, education, and, if $\omega \propto 1/\text{Income}$, normal goods.
- "Positive Correlation": $\omega(\theta)$ is increasing in θ .
 - high-demand consumers tend to have higher need for redistribution.
 - ▶ e.g., staple foods, public transportation, and, if $\omega \propto 1$ / Income, inferior goods.

Correlation Assumption

Proposition. For any subsidy P^{σ} , the social planner would prefer to make a lump-sum transfer of $\mathbf{E}_{\theta}[\Sigma(q^{\sigma}(\theta))]$ to all consumers than the subsidy outcome.

Proof: By definition of U^{LF} and correlation inequality,

$$\underbrace{\int_{\Theta} \omega(\theta) \textbf{\textit{U}}^{\sigma}(\theta) - \alpha \Sigma(\textbf{\textit{q}}^{\sigma}(\theta)) \, d\textbf{\textit{F}}(\theta)}_{\text{objective given } \textbf{\textit{P}}^{\sigma}} = \int_{\Theta} \omega(\theta) [\theta \textbf{\textit{v}}(\textbf{\textit{q}}^{\sigma}(\theta)) - \textbf{\textit{c}} \textbf{\textit{q}}^{\sigma}(\theta) + \Sigma(\textbf{\textit{q}}^{\sigma}(\theta))] - \alpha \Sigma(\textbf{\textit{q}}^{\sigma}(\theta)) \, d\textbf{\textit{F}}(\theta)}_{\leq \int_{\Theta} \omega(\theta) [\textbf{\textit{U}}^{\mathsf{LF}}(\theta) + \Sigma(\textbf{\textit{q}}^{\sigma}(\theta))] - \alpha \Sigma(\textbf{\textit{q}}^{\sigma}(\theta)) \, d\textbf{\textit{F}}(\theta)}_{\leq \int_{\Theta} \omega(\theta) [\textbf{\textit{U}}^{\mathsf{LF}}(\theta) + \mathbf{E}_{\theta}[\Sigma(\textbf{\textit{q}}^{\sigma}(\theta))]] \, d\textbf{\textit{F}}(\theta) - \alpha \, \mathbf{E}_{\theta}[\Sigma(\textbf{\textit{q}}^{\sigma}(\theta))]}_{\text{objective given cash payment } \mathbf{E}_{\theta} \Sigma(\textbf{\textit{q}}^{\sigma}(\theta))}_{\leq 0}. \ \Box$$

Theorem 1 (Negative Correlation, part). The social planner subsidizes consumption only if $\mathbf{E}_{\theta}[\omega(\theta)] > \alpha$ (and cash transfers are unavailable).

Model

When To Subsidize?

Theorem 1 (Negative Correlation). The social planner subsidizes consumption if and only if $\mathbf{E}_{\theta}[\omega(\theta)] > \alpha$ (and cash transfers are unavailable).

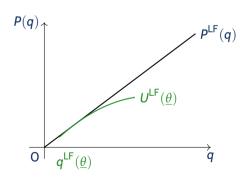

When To Subsidize?

Theorem 1 (Negative Correlation). The social planner subsidizes consumption if and only if $\mathbf{E}_{\theta}[\omega(\theta)] > \alpha$ (and cash transfers are unavailable).

Proof of "if" direction:

Suppose $\mathbf{E}_{\theta}[\omega(\theta)] > \alpha$. We identify a subsidy schedule improving over laissez-faire.

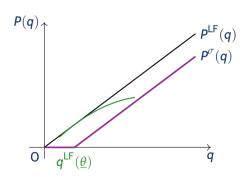

When To Subsidize?

Theorem 1 (Negative Correlation). The social planner subsidizes consumption if and only if $\mathbf{E}_{\theta}[\omega(\theta)] > \alpha$ (and cash transfers are unavailable).

Proof of "if" direction:

Suppose $\mathbf{E}_{\theta}[\omega(\theta)] > \alpha$. We identify a subsidy schedule improving over laissez-faire.

 P^{σ} is outcome-equivalent to a cash transfer of $cq^{\mathsf{LF}}(\underline{\theta})$ to all consumers, and improves over laissez-faire because $\mathbf{E}_{\theta}[\omega(\theta)] > \alpha$.

How to Design Subsidies?

Mechanism Design Reformulation

Revelation principle \implies it suffices to consider direct mechanisms (q, t) consisting of:

- ▶ an allocation function $q: [\underline{\theta}, \overline{\theta}] \to [0, A]$ denoting total quantity consumed by type θ ;
- ▶ a payment rule $t : [\underline{\theta}, \overline{\theta}] \to \mathbb{R}$ denoting *total* payment by type θ ,

satisfying incentive-compatibility,

$$heta \in rg \max_{\hat{ heta} \in \Theta} \left\{ heta v(q(\hat{ heta})) - t(\hat{ heta})
ight\} ext{ for all } heta \in \Theta.$$
 (IC)

odel Scope Chara

Model

Economic Implications

With negative correlation between ω and θ :

#1. Lump-sum cash transfers are always more progressive than subsidies.

Economic Implications

With negative correlation between ω and θ :

- # 1. Lump-sum cash transfers are always more progressive than subsidies.
- # 2. If cash transfers are unavailable, linear subsidies are never optimal.
 - # 2a. Optimal subsidies are "all or none": active subsidy programs should always incorporate a free allocation ("public option").
 - # 2b. If any consumer has $\omega < \alpha$, optimal subsidies are capped in quantity.

Deriving the Optimal Mechanism

Solving for the Optimal Mechanism

$$\label{eq:max_alpha} \begin{split} \max_{q} \alpha \int_{\underline{\theta}}^{\overline{\theta}} \left[J(\theta) v(q(\theta)) - cq(\theta) \right] \; \mathrm{d}F(\theta), \\ \mathrm{s.t.} \; q \; \mathrm{nondecreasing \; and} \; q(\theta) \geq q^{\mathsf{LF}}(\theta). \end{split}$$

Solving for the Optimal Mechanism

$$\max_{q} \alpha \int_{\theta}^{\overline{\theta}} \left[J(\theta) v(q(\theta)) - cq(\theta) \right] dF(\theta),$$

s.t. q nondecreasing and $q(\theta) \ge q^{\mathsf{LF}}(\theta)$.

Guess 1: Pointwise maximizer

$$q(\theta) = (\mathbf{v}')^{-1} \left(\frac{\mathbf{c}}{J(\theta)} \right) = D(\mathbf{c}, J(\theta)).$$

Model

$$\max_{q} \alpha \int_{\underline{\theta}}^{\overline{\theta}} \left[J(\theta) v(q(\theta)) - cq(\theta) \right] \, \mathrm{d}F(\theta),$$

s.t. q nondecreasing and $q(\theta) \ge q^{\mathsf{LF}}(\theta)$.

Guess 1: Pointwise maximizer

$$q(\theta) = (\mathbf{v}')^{-1} \left(\frac{\mathbf{c}}{J(\theta)} \right) = D(\mathbf{c}, J(\theta)).$$

Demand $D(c, \cdot)$ is increasing, so: q nondecreasing $\iff J(\theta)$ nondecreasing. $q > q^{LF} \iff D(c, J(\theta)) > D(c, \theta) \iff J(\theta) > \theta$.

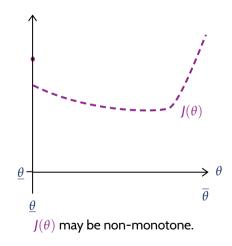

$$\max_{q} \alpha \int_{\underline{\theta}}^{\overline{\theta}} \left[J(\theta) v(q(\theta)) - cq(\theta) \right] dF(\theta),$$

s.t. q nondecreasing and $q(\theta) \ge q^{\mathsf{LF}}(\theta)$.

Guess 1: Pointwise maximizer

$$q(\theta) = (\mathbf{v}')^{-1} \left(\frac{\mathbf{c}}{J(\theta)} \right) = D(\mathbf{c}, J(\theta)).$$

Demand $D(c, \cdot)$ is increasing, so: q nondecreasing $\iff J(\theta)$ nondecreasing. $q > q^{\mathsf{LF}} \iff \mathsf{D}(\mathsf{c},\mathsf{J}(\theta)) > \mathsf{D}(\mathsf{c},\theta) \iff \mathsf{J}(\theta) > \theta.$

Derivation

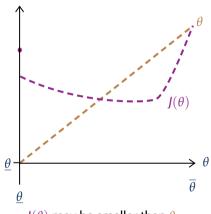

$$\max_{q} \alpha \int_{\underline{\theta}}^{\overline{\theta}} \left[J(\theta) v(q(\theta)) - cq(\theta) \right] dF(\theta),$$
s.t. q nondecreasing and $q(\theta) \ge q^{\mathsf{LF}}(\theta)$.

Guess 1: Pointwise maximizer

$$q(\theta) = (\mathbf{v}')^{-1} \left(\frac{\mathbf{c}}{J(\theta)} \right) = D(\mathbf{c}, J(\theta)).$$

Demand $D(c,\cdot)$ is increasing, so: q nondecreasing $\iff J(\theta)$ nondecreasing. $q \geq q^{\mathsf{LF}} \iff D(c,J(\theta)) \geq D(c,\theta) \iff J(\theta) \geq \theta$.

 $J(\theta)$ may be smaller than θ .

construction → pooling condition and continuity

Verifying *H* from Theorem 2

Because $q^*(\theta) = D(c, H(\theta))$, for any feasible q

$$\int_{\Theta} \underbrace{\left[H(\theta) v(q^*(\theta)) - cq^*(\theta) \right]}_{\text{surplus of type } H(\theta) \text{ at } D(c, H(\theta))} \, dF(\theta) \geq \int_{\Theta} \underbrace{\left[H(\theta) v(q(\theta)) - cq(\theta) \right]}_{\text{surplus of type } H(\theta) \text{ at } q(\theta)} \, dF(\theta).$$

Verifying *H* from Theorem 2

Because $q^*(\theta) = D(c, H(\theta))$, for any feasible q

$$\int_{\Theta} \underbrace{\left[H(\theta) v(q^*(\theta)) - cq^*(\theta) \right]}_{\text{surplus of type } H(\theta) \text{ at } D(c,H(\theta))} \, dF(\theta) \geq \int_{\Theta} \underbrace{\left[H(\theta) v(q(\theta)) - cq(\theta) \right]}_{\text{surplus of type } H(\theta) \text{ at } q(\theta)} \, dF(\theta).$$

We want to show, for any feasible q

$$\underbrace{\int_{\Theta} [J(\theta)v(q^*(\theta)) - cq^*(\theta)] \, \mathrm{d}F(\theta)}_{\text{objective at } q^*} \geq \underbrace{\int_{\Theta} [J(\theta)v(q(\theta)) - cq(\theta)] \, \mathrm{d}F(\theta)}_{\text{objective at feasible } q}.$$

Verifying *H* from Theorem 2

Because $q^*(\theta) = D(c, H(\theta))$, for any feasible q

$$\int_{\Theta} \underbrace{\left[H(\theta) v(q^*(\theta)) - cq^*(\theta) \right]}_{\text{surplus of type } H(\theta) \text{ at } D(c, H(\theta))} \, \operatorname{d}\! F(\theta) \geq \int_{\Theta} \underbrace{\left[H(\theta) v(q(\theta)) - cq(\theta) \right]}_{\text{surplus of type } H(\theta) \text{ at } q(\theta)} \, \operatorname{d}\! F(\theta).$$

We want to show, for any feasible q

$$\underbrace{\int_{\Theta} [J(\theta) v(q^*(\theta)) - cq^*(\theta)] \, \mathrm{d}F(\theta)}_{\text{objective at } q^*} \geq \underbrace{\int_{\Theta} [J(\theta) v(q(\theta)) - cq(\theta)] \, \mathrm{d}F(\theta)}_{\text{objective at feasible } q}.$$

Subtracting, it suffices to show, for any feasible q

$$\int_{\Theta} [J(\theta) - H(\theta)][v(q^*(\theta)) - v(q(\theta))] dF(\theta) \ge 0.$$

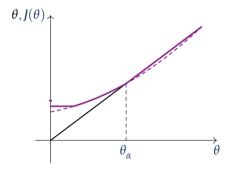

To show $\int_{\Theta} [J(\theta) - H(\theta)][v(q^*(\theta)) - v(q(\theta))] dF(\theta) \ge 0$.

To show $\int_{\Theta} [J(\theta) - H(\theta)] [v(q^*(\theta)) - v(q(\theta))] dF(\theta) \ge 0$.

There are three possibilities for H, partitioning Θ into intervals:

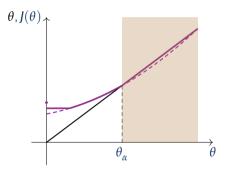

To show $\int_{\Theta} [J(\theta) - H(\theta)] [v(q^*(\theta)) - v(q(\theta))] dF(\theta) \ge 0$.

There are three possibilities for H, partitioning Θ into intervals:

1.
$$H(\theta) = \theta$$
: by construction $J(\theta) \le \theta = H(\theta)$ and $v(q(\theta)) \ge v(q^*(\theta)) \rightsquigarrow \text{integrand} \ge 0$.

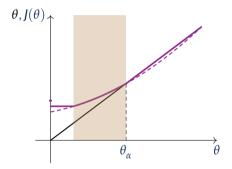

To show $\int_{\Theta} [J(\theta) - H(\theta)] [v(q^*(\theta)) - v(q(\theta))] dF(\theta) \ge 0.$

There are three possibilities for H, partitioning Θ into intervals:

#1. $H(\theta) = \theta$: by construction $I(\theta) < \theta = H(\theta)$ and $v(q(\theta)) > v(q^*(\theta)) \sim \text{integrand} > 0.$

2. $H(\theta) = I(\theta)$: integrand = 0.

Derivation

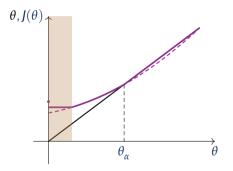

To show
$$\int_{\Theta} [J(\theta) - H(\theta)] [v(q^*(\theta)) - v(q(\theta))] dF(\theta) \ge 0$$
.

There are three possibilities for H, partitioning Θ into intervals:

1.
$$H(\theta) = \theta$$
: by construction $J(\theta) \le \theta = H(\theta)$ and $v(q(\theta)) \ge v(q^*(\theta)) \rightsquigarrow \text{integrand} \ge 0$.

2.
$$H(\theta) = J(\theta)$$
: integrand = 0.

3.
$$H(\theta) = \overline{J|_{[\underline{\theta},\theta_{\alpha}]}}(\theta) \neq J(\theta)$$
:
technical lemma \leadsto on any such interval Θ_i , $H = \overline{J|_{\Theta_i}}$
 \leadsto optimality of $D(c,H(\theta))$ in problem on Θ_i without (LB)
 \Longrightarrow same variational inequality characterizes optimality. \square

Summing Up

Proof approach:

- Guess form of solution $q^*(\theta) = D(c, H(\theta))$.
- ldentify $H(\theta)$ which is continuous, $\geq \theta$, and satisfies the pooling condition.
- Verify optimality using variational inequalities.

Same method of solution works for general $\omega \sim$ see paper.

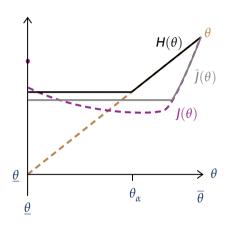

Role of Topping Up

Comparing optimum with and without (LB) constraint, $H(\theta)$ can exceed \bar{l} for all types.

 \sim Inability to tax causes upward distortion of *all* types

It is not optimal to calculate optimal subsidy/tax and set taxes to zero.

Highlights distinction from Mirrleesian marginal approach (FOC $\not\sim$ optimum).

Conclusion

Appendix

1. What are the features of subsidy designs in practice?

When? Theorem 1 \rightarrow scope of intervention larger with positive correlation (max $\omega > \alpha$) than negative correlation ($\mathbf{E}[\omega] > \alpha$).

In practice, many government programs appear to select goods consumed disproportionately by needy.

How? Significant differences in marginal subsidy schedules observed in practice:

Larger subsidies for low q

- Food stamps (SNAP)
- Womens, Infants & Children (WIC) Program
- Housing Choice (Section 8) Vouchers
- Lifeline (Telecomm. Assistance) Program

Larger subsidies for high q

- Public transit fare capping
- Pharmaceutical subsidy programs
- Government-subsidized childcare places.

Discussion

Proposition. Linear subsidies are never optimal.

Intuition: no distortion at the top $(J(\overline{\theta}) = \overline{\theta}) \sim$ linear subsidies never optimal.

Proposition. Linear subsidies are never optimal.

Intuition: no distortion at the top $(J(\overline{\theta}) = \overline{\theta}) \sim$ linear subsidies never optimal.

Implication: production subsidies are suboptimal for redistribution.

Proposition. Linear subsidies are never optimal.

Intuition: no distortion at the top ($J(\overline{\theta}) = \overline{\theta}$) \sim linear subsidies never optimal.

Implication: production subsidies are suboptimal for redistribution.

Social planner can always improve over linear subsidy by implementing:

- a cap on the subsidy paid to a consumer (as in negative correlation),
- a floor on eligibility for the subsidy (as in positive correlation), or
- a free endowment of the good to all consumers.

Gains from nonlinear subsidization can be arbitrarily large compared to gains from linear subsidization.

3. How Do Changes in Market Primitives Affect Optimal Subsidies?

Question: How do optimal subsidies change when

- (a) the social planner's desire to redistribute to each consumer increases?
- (b) the correlation between demand and welfare weight increases?
- (c) the marginal cost of production decreases?

3. How Do Changes in Market Primitives Affect Optimal Subsidies?

Question: How do optimal subsidies change when

- (a) the social planner's desire to redistribute to each consumer increases?
- (b) the correlation between demand and welfare weight increases?
- (c) the marginal cost of production decreases?

Short Answer: Each cause the optimal subsidy program to be more generous.

But (a) and (b) cause $J(\theta)$ to increase for each $\theta \sim$ a larger set of consumers subsidized. (c) does not.

Model

Scope

Characterization

4. When Does the Planner Benefit from Restricting Topping Up?

In some markets (e.g., public housing), the social planner may be able to restrict subsidy recipients from topping up in private market \sim opt-in (or out) of subsidy program.

4. When Does the Planner Benefit from Restricting Topping Up?

In some markets (e.g., public housing), the social planner may be able to restrict subsidy recipients from topping up in private market \sim opt-in (or out) of subsidy program.

In Kang and Watt (2024), we characterize optimal subsidy mechanism under such restrictions. These lead to different (weaker) type-dependent outside option constraints:

average price \leq c \Leftrightarrow majorization constraint on q.

4. When Does the Planner Benefit from Restricting Topping Up?

In some markets (e.g., public housing), the social planner may be able to restrict subsidy recipients from topping up in private market \sim opt-in (or out) of subsidy program.

In Kang and Watt (2024), we characterize optimal subsidy mechanism under such restrictions. These lead to different (weaker) type-dependent outside option constraints:

average price \leq c \Leftrightarrow majorization constraint on q.

Proposition.

- (a) "Negative Correlation": ω decreasing in $\theta \sim$ planner benefits from preventing topping up iff $\max \omega > \alpha$.
- (b) "Positive Correlation": ω increasing in $\theta \sim$ planner never benefits from preventing topping up.

Intuition: Planner offers subsidies tied to consumption level favored by high ω types.

<u>Implication</u>: Positive correlation between demand and welfare weights reduces the need to enforce topping up restrictions.

Conclusion

Appendix

Equilibrium Effects

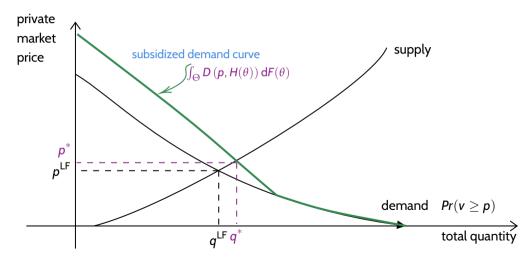

Our baseline model shuts down equilibrium effects of government subsidies on private market prices.

Empirical evidence of price effects from government subsidy programs, e.g.:

- public housing (Diamond and McQuade, 2019; Baum-Snow and Marion, 2009)
- pharmaceuticals (Atal et al., 2021)
- public schools (Dinerstein and Smith, 2021)
- school lunches (Handbury and Moshary, 2021)

Equilibrium Effects

Our results extend directly to imperfectly elastic supply curves:

Extensions

Private Market Taxation

Our baseline model assumes the planner cannot tax the private market.

Taxation of private market reduces consumers' outside option, relaxing the (LB) constraint. If taxation is costly (e.g., because of distortions on ineligible consumers):

Proposition. Suppose the planner faces a convex cost $\Gamma(\tau)$ for taxation of the private market. Then there exists an optimal tax level τ^* and subsidy program for eligible consumers satisfying

$$q^*(\theta) = D(H_{\tau^*}(\theta)),$$

where $H_{\tau^*}(\theta) \leq H(\theta)$.

Extensions

Budget Constraints and Endogenous Welfare Weights

In our baseline model, $\omega(\cdot)$ and α are taken exogenously.

Our model can be extended to allow weights to be endogenous (cf. Pai and Strack, 2024):

- $ightharpoonup \alpha \iff$ Lagrange multiplier on the social planner's budget constraint.
- \blacktriangleright $\omega(\theta)$ \iff the marginal value of money for a consumer with concave preferences

$$\varphi\left(\theta v(q)+I-t\right)$$
 ,

and income $I \sim G_{\theta}$, known but not observed by the social planner, then

$$\omega(\theta) = \mathbf{E}_{I \sim \mathsf{G}_{\theta}} [\varphi'(\theta \mathsf{v}(q(\theta)) + I - t(\theta))].$$

Conclusion

Takeaways for Subsidy Policy:

- Linear subsidies (e.g., production subsidies) are never optimal.
- When and how to subsidize depends on correlation between demand and need.
 - With negative correlation (many goods), why not lump-sum cash transfers? ("tortilla subsidy" vs. Progresa).
 - Goods with positive correlation are ideal candidates for subsidies (e.g., public transport) but these should have floors to improve targeting.

model Scope

Takeaways for Subsidy Policy:

- Linear subsidies (e.g., production subsidies) are never optimal.
- ► When and how to subsidize depends on correlation between demand and need.
 - With negative correlation (many goods), why not lump-sum cash transfers? ("tortilla subsidy" vs. Progresa).
 - Goods with positive correlation are ideal candidates for subsidies (e.g., public transport) but these should have floors to improve targeting.

e.g. Plan for Action on Regional Transit (Dec. 2023, Chicago Metropolitan Agency for Planning)

Takeaways for Subsidy Policy:

 - Goods with positive correlation are ideal candidates for subsidies (e.g., public transport) but these should have floors to improve targeting.

e.g. Plan for Action on Regional Transit (Dec. 2023, Chicago Metropolitan Agency for Planning)

Equity

Transit connects people to opportunities

Inequity in the form of disparities — including in employment, health, educational attainment, and income — will persist for transit riders, especially from households with low income, communities of color, seniors, and residents with disabilities.

Leverage the transportation network to promote resiliency and inclusive growth.

Long-term economic prosperity requires that the region address inequity issues and take action to increase opportunity and improve quality of life for all residents. Transit plays a key role in creating pathways to opportunity; our region and its communities are stronger when everyone has access to reliable and affordable transportation.

Takeaways for Subsidy Policy:

- Linear subsidies (e.g., production subsidies) are never optimal.
- ► When and how to subsidize depends on correlation between demand and need.
 - With negative correlation (many goods), why not lump-sum cash transfers? ("tortilla subsidy" vs. Progresa).
 - Goods with positive correlation are ideal candidates for subsidies (e.g., public transport) but these should have floors to improve targeting.

e.g. Plan for Action on Regional Transit (Dec. 2023, Chicago Metropolitan Agency for Planning)

Recommendation: Establish regional fare subsidy programs that include youth and riders with low income

Operating cost: Varies depending on program, with scale of costs ranging from \$15-150M annually (depending on discount, eligibility, and uptake).

Capital: N/A

Recommendation: Implement fare capping

Operating cost: Minimal but depends on implementation. There are fare revenue implications, but pass rates could be adjusted to achieve revenue neutrality if desired.

Capital: \$25-\$50M

lodel Scope Characterization Derivation Positive Correlation Discussion Extensions **Conclusion** Appendix

Takeaways for Subsidy Policy:

- Linear subsidies (e.g., production subsidies) are never optimal.
- When and how to subsidize depends on correlation between demand and need.
 - With negative correlation (many goods), why not lump-sum cash transfers? ("tortilla subsidy" vs. Progresa).
 - Goods with positive correlation are ideal candidates for subsidies (e.g., public transport) but these should have floors to improve targeting.

Technical Contribution:

- We show how to solve mechanism design problems with lower-bound constraints caused by type-dependent outside options.
- Similar mechanism design problems arise in other contexts, e.g., subsidy design with other objectives (externalities, paternalism); exclusive contracting (topping up = non-exclusive contracting, no topping up = exclusive contracting.).
- Future avenue: incorporating adverse selection, as may be needed to study healthcare subsidies.

Assumption: No Lump-Sum Cash Transfers

Note: This constraint only binds if $\mathbf{E}_{\theta}[\omega(\theta)] > \alpha$.

Possible reasons:

- Institutional: subsidies designed by government agency without tax/transfer powers.
- Political: Liscow and Pershing (2022) find U.S. voters prefer in-kind redistribution to cash transfers.
- Household Economics: Currie (1994) finds in-kind redistribution has stronger benefits for children than cash transfer programs.
- ▶ Pedagogical: to contrast when the assumption is binding (~ cash transfers preferred to subsidies) versus non-binding (vice versa).
- Model: without NLS constraint, the social planner would want to make unbounded cash transfers when $\mathbf{E}[\omega] > \alpha$.

When to Subsidize (General): Proof by Picture

Theorem 1. Social planner subsidizes if and only if there exists a type $\hat{\theta}$ for which $\mathbf{E}_{\theta}[\omega(\theta) \mid \theta \geq \hat{\theta}] > \alpha$.

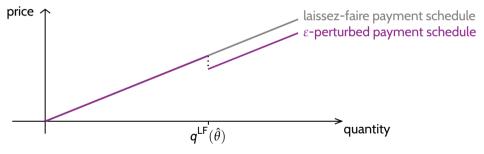

Suppose $\mathbf{E}_{\theta}[\omega(\theta)|\theta \geq \hat{\theta}] > \alpha$: we construct a subsidy schedule increasing weighted surplus.

When to Subsidize (General): Proof by Picture

Theorem 1. Social planner subsidizes if and only if there exists a type $\hat{\theta}$ for which $\mathbf{E}_{\theta}[\omega(\theta) \mid \theta \geq \hat{\theta}] > \alpha$.

Suppose $\mathbf{E}_{\theta}[\omega(\theta)|\theta \geq \hat{\theta}] > \alpha$: we construct a subsidy schedule increasing weighted surplus.

 ε -perturbation increases utility of types $\geq \hat{\theta}$, net benefit ε $\mathbf{E}_{\theta}[\omega(\theta) - \alpha | \theta \geq \hat{\theta}]$.

When to Subsidize (General): Proof by Picture

Social planner subsidizes if and only if there exists a type $\hat{\theta}$ for which $\mathbf{E}_{\theta}[\omega(\theta) \mid \theta > \hat{\theta}] > \alpha.$

Suppose $\mathbf{E}_{\theta}[\omega(\theta)|\theta \geq \hat{\theta}] > \alpha$: we construct a subsidy schedule increasing weighted surplus.

 ε -perturbation increases utility of types $\geq \hat{\theta}$, net benefit $\varepsilon \mathbf{E}_{\theta}[\omega(\theta) - \alpha | \theta \geq \hat{\theta}]$.

But consumption is distorted for $O(\sqrt{\varepsilon})$ set of types near (but below) $\hat{\theta}$, at cost $< O(\sqrt{\varepsilon})\varepsilon$.

 \sim Benefits > costs for small enough ε . Note: Argument relies on nonlinearity.

Topping Up ← Lower-Bound (1/2)

Suppose $q(\theta) \ge q^{\mathsf{LF}}(\theta)$. We want to show total subsidies S(z) is increasing in z.

1.
$$t(\underline{\theta}) \leq cq(\underline{\theta})$$
 by (IR):

$$t(\underline{\theta}) \leq \underline{\theta} v(q(\underline{\theta})) - \underline{\theta} v(q^{\mathsf{LF}}(\underline{\theta})) + cq^{\mathsf{LF}}(\underline{\theta}),$$

and $\underline{\theta}v(q^{\mathsf{LF}}(\underline{\theta})) - cq^{\mathsf{LF}}(\underline{\theta}) \ge \underline{\theta}v(q(\underline{\theta})) - cq(\underline{\theta})$ by definition of q^{LF} , so $t(\underline{\theta}) \le cq(\underline{\theta})$.

Topping Up \leftarrow Lower-Bound (2/2)

2. The marginal price of any units purchased is no greater than c by (IC):

$$\begin{aligned} t(\theta') - t(\theta) &= \left[\theta' v(q(\theta')) - U(\underline{\theta}) - \int_{\underline{\theta}}^{\theta'} v(q(s)) \, \mathrm{d}s \right] - \left[\theta v(q(\theta)) - U(\underline{\theta}) - \int_{\underline{\theta}}^{\theta} v(q(s)) \, \mathrm{d}s \right] \\ &= \theta' v(q(\theta')) - \theta v(q(\theta)) - \int_{\theta}^{\theta'} v(q(s)) \, \mathrm{d}s \\ &= \int_{\theta}^{\theta'} s v'(q(s)) \, \mathrm{d}q(s). \end{aligned}$$

But if $q(\theta) \ge q^{\mathsf{LF}}(\theta)$, then concavity of v implies $v'(q(\theta)) \le v'(q^{\mathsf{LF}}(\theta)) = c/\theta$, so $t(\theta') - t(\theta) < c[a(\theta') - a(\theta)].$

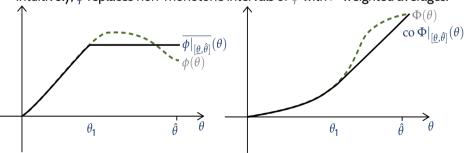

Ironing

Let ϕ be a (generalized) function and $\Phi:\theta\mapsto\int_{\underline{\theta}}^{\theta}\phi(s)\,\mathrm{d}F(s)$. Then $\overline{\phi}$ is the monotone function satisfying

$$\text{ for all } \theta \in [\underline{\theta}, \hat{\theta}], \qquad \int_{\theta}^{\theta} \overline{\phi}(s) \ \mathsf{d}F(s) = \mathsf{co}\, \Phi(\theta).$$

Intuitively, $\overline{\phi}$ replaces non-monotone intervals of ϕ with F-weighted averages.

Rewriting the Mechanism Design Problem

The social planner maximizes weighted total surplus

$$\max_{(q,t)} \int_{\underline{\theta}}^{\overline{\theta}} \left[\omega(\theta) \underbrace{\left[\theta v(q(\theta)) - t(\theta) \right]}_{\text{consumer surplus}} - \alpha \underbrace{\left[cq(\theta) - t(\theta) \right]}_{\text{total cost}} \right] \, \mathrm{d}F(\theta),$$

subject to (IC), (LB), (IR), and (NLS).

Rewriting the Mechanism Design Problem

$$\max_{\substack{q \text{ non-decreasing, } U(\underline{\theta}) \geq U^{\mathsf{LF}}(\underline{\theta})}} \mathbf{E}_{\theta}[\omega(\theta) - \alpha] U(\underline{\theta}) + \alpha \int_{\underline{\theta}}^{\overline{\theta}} \left[\left(\theta + \frac{\int_{\underline{\theta}}^{\overline{\theta}} [\omega(s) - \alpha] \mathrm{d}F(s)}{\alpha f(\theta)} \right) v(q(\theta)) - cq(\theta) \right] \, \mathrm{d}F(\theta),$$

subject to (LB), (IR), and (NLS).

#1. Apply Myerson's (1981) Lemma and Milgrom and Segal (2002) envelope theorem to express objective in terms of $U(\underline{\theta})$ and $q(\theta)$ non-decreasing.

Rewriting the Mechanism Design Problem

$$\max_{\substack{q \text{ non-decreasing, } U(\underline{\theta}) \geq U^{\mathsf{LF}}(\underline{\theta})}} \mathbf{E}_{\theta}[\omega(\theta) - \alpha] U(\underline{\theta}) + \alpha \int_{\underline{\theta}}^{\overline{\theta}} \left[\left(\theta + \frac{\int_{\underline{\theta}}^{\overline{\theta}} [\omega(s) - \alpha] \mathrm{d}F(s)}{\alpha f(\theta)} \right) v(q(\theta)) - cq(\theta) \right] \, \mathrm{d}F(\theta),$$

subject to (LB), (IR), and (NLS).

- #1. Apply Myerson's (1981) Lemma and Milgrom and Segal (2002) envelope theorem to express objective in terms of $U(\theta)$ and $q(\theta)$ non-decreasing.
- #2. Suffices to enforce (IR) and (NLS) only for lowest type θ because $U(\theta) U^{LF}(\theta)$ and $t(\theta)$ are nondecreasing by (IC) and (LB).

- \rightarrow Low cost of public funds: if $\mathbf{E}[\omega(\theta)] > \alpha$, choose $U(\underline{\theta}) = \underline{\theta} \mathbf{v}(\mathbf{q}(\underline{\theta}))$.
- \sim High cost of public funds: if $\mathbf{E}[\omega(\theta)] < \alpha$. choose $U(\theta) = U^{\mathsf{LF}}(\theta)$.

Rewriting the Mechanism Design Problem

$$\max_{q \text{ non-decreasing}} \alpha \int_{\underline{\theta}}^{\overline{\theta}} \left[J(\theta) v(q(\theta)) - cq(\theta) \right] \ \mathrm{d}F(\theta) + (\text{terms independent of } q),$$

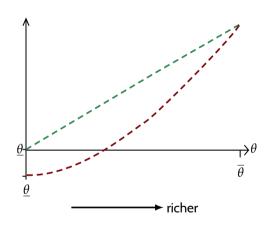

subject to (LB): $q(\theta) \geq q^{\mathsf{LF}}(\theta)$, where the virtual type

$$J(\theta) = \underbrace{\frac{\theta}{\text{efficiency}}}_{\text{efficiency}} + \underbrace{\frac{\int_{\theta}^{\overline{\theta}} [\omega(s) - \alpha] \mathrm{d}F(s)}{\alpha f(\theta)}}_{\text{redistributive motive}} + \underbrace{\frac{\max\{\mathbf{E}_{\theta}[\omega(\theta) - \alpha], \mathbf{O}\}\underline{\theta}\delta_{\theta = \underline{\theta}}}{\alpha f(\theta)}}_{\text{(NLS) constraint}}$$

Call $J(\theta) - \theta$ the "distortion term."

Decreasing Welfare Weights, High Cost of Public Funds

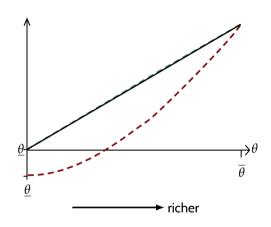

High cost of public funds: $\mathbf{E}[\omega(\theta)] < \alpha$.

$$J(\theta) = \theta + \frac{\int_{\theta}^{\overline{\theta}} \left[\omega(s) - \alpha \right] \, dF(s)}{\alpha f(\theta)}$$

is always *below* lower bound θ because distortion is single-crossing from above, negative at θ and zero at $\overline{\theta}$.

Decreasing Welfare Weights, High Cost of Public Funds

High cost of public funds: $\mathbf{E}[\omega(\theta)] \leq \alpha$.

$$J(\theta) = \theta + \frac{\int_{\theta}^{\overline{\theta}} \left[\omega(s) - \alpha \right] \, dF(s)}{\alpha f(\theta)}$$

is always *below* lower bound θ because distortion is single-crossing from above, negative at $\underline{\theta}$ and zero at $\overline{\theta}$.

 \sim Subsidy type ${\it H}(\theta)=\theta$ and optimal allocation is laissez-faire.

Optimal Mechanism (Arbitrary Correlation)

Theorem 2 (General). The optimal subsidy allocation rule is unique, continuous and satisfies

$$q^*(\theta) = D\left(c, H(\theta)\right), \text{ where } H(\theta) = \begin{cases} \theta & \text{if } \overline{J|_{[\underline{\theta}, \theta]}}(\theta) \leq \theta, \\ \overline{J_{[\underline{\theta}, \kappa_+(\theta)]}}(\theta) & \text{otherwise,} \end{cases}$$

and $\kappa_+(\theta)=\inf\left\{\hat{\theta}\geq\theta:\overline{J|_{[\underline{\theta},\hat{\theta}]}}(\hat{\theta})\leq\hat{\theta}\right\}$ or $\overline{\theta}$, if that set is empty.

"Double" ironing construction of $H(\theta)$ ensures $H(\theta) > \theta$, equivalent to (LB) given expression for q^* .

 \rightarrow subsidized demand curve $\overline{D}(p) = \int_{\Theta} (v')^{-1} (p/H(\theta)) dF(\theta)$.

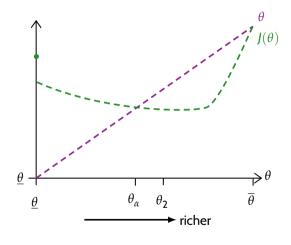

Decreasing Welfare Weights, Low Cost of Public Funds

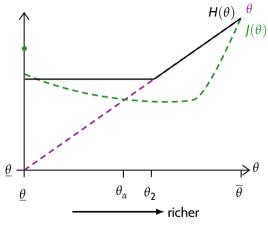

Low cost of public funds: $\mathbf{E}[\omega(\theta)] > \alpha$.

$$J(\theta) = \theta + \frac{\int_{\theta}^{\overline{\theta}} [\omega(s) - \alpha] \, \mathrm{d}F(s) + (\mathsf{E}_{\theta}[\omega(\theta)] - \alpha) \underline{\theta} \delta_{\theta = \underline{\theta}}}{\alpha f(\theta)} \text{ crosses lower bound constraint } \theta \text{ from } above \text{ because distortion term is single-crossing from above, positive at } \theta \text{ and zero at } \overline{\theta}.$$

Decreasing Welfare Weights, Low Cost of Public Funds

Low cost of public funds: $\mathbf{E}[\omega(\theta)] > \alpha$.

$$J(\theta) = \theta + \frac{\int_{\theta}^{\overline{\theta}} [\omega(s) - \alpha] \; \mathrm{d}F(s) + (\mathbf{E}_{\theta}[\omega(\theta)] - \alpha)\underline{\theta}\delta_{\theta = \underline{\theta}}}{\alpha f(\theta)} \; \text{crosses}$$
 lower bound constraint θ from above because distortion term is single-crossing from above, positive at θ and zero at $\overline{\theta}$.

 \sim Subsidy type $H(\theta) > \theta$ for $\theta \leq \theta_2$. There is a free endowment of $q^{\mathsf{LF}}(\theta_2)$, which strictly exceeds $q^{\mathsf{F}}(\theta)$ for $\theta \leq \theta_2 \dots but$ planner always prefers a lump-sum subsidy.

Deriving

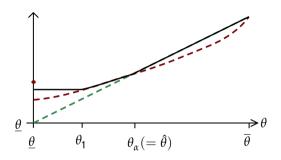

▶ return

Decreasing Welfare Weight, Low Cost of Public Funds

Other possibilities:

Free endowment + quantity-dependent subsidies distorting all types' consumption upwards (no topping up).

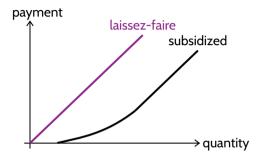

Free endowment + quantity-dependent subsidies up to a cap (high types top up in private market).

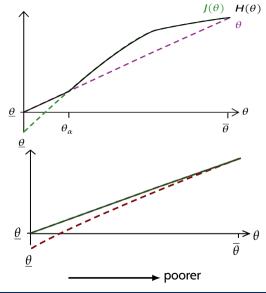

Decreasing Welfare Weight, Low Cost of Public Funds

Payment schedule:

Increasing Welfare Weights, High Cost of Public Funds

High cost of public funds: $\mathbf{E}[\omega(\theta)] \leq \alpha$.

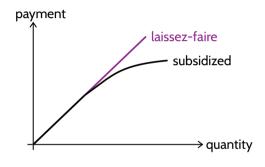

$$J(\theta) = \theta + \frac{\int_{\theta}^{\overline{\theta}} \left[\omega(s) - \alpha \right] \, dF(s)}{\alpha f(\theta)}$$

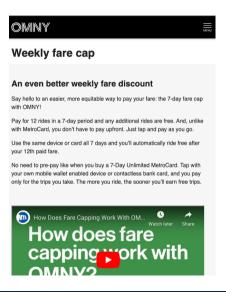

can cross lower-bound θ from below because the distortion term is single-crossing from below, negative at $\underline{\theta}$ and zero at $\overline{\theta}$.

 \sim Subsidy type can exceed θ for high types: implemented by offering discounts for consumption above a minimum level... preferred by planner to lump-sum transfer.

Increasing Welfare Weights, High Cost of Public Funds

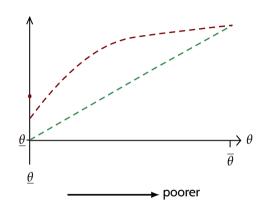

Payment schedule:

Increasing Welfare Weights, Low Cost of Public Funds

Low cost of public funds: $\mathbf{E}[\omega(\theta)] > \alpha$. exceeds lower-bound θ because the distortion term is

single-crossing from below, positive at θ and zero at

 \sim Subsidy type exceeds θ for all types: implemented via a free allocation and discounts for additional consumption. No consumers top up.

Deriving

 $\overline{\theta}$.

Increasing Welfare Weights, Low Cost of Public Funds

Low cost of public funds: $\mathbf{E}[\omega(\theta)] > \alpha$.

$$J(\theta) = \theta + \frac{\int_{\theta}^{\overline{\theta}} [\omega(s) - \alpha] \; \mathrm{d}F(s) + (\mathbf{E}_{\theta}[\omega(\theta)] - \alpha) \underline{\theta} \delta_{\theta = \underline{\theta}}}{\alpha f(\theta)}$$
 always exceeds lower-bound θ because the distortion term is single-crossing from below, positive at $\underline{\theta}$ and zero at $\overline{\theta}$.

 \sim Subsidy type exceeds θ for all types: implemented via a free allocation and discounts for additional consumption. No consumers top up.

Discussion

Theorem 1 → scope of intervention larger for "inferior goods" than "normal goods."

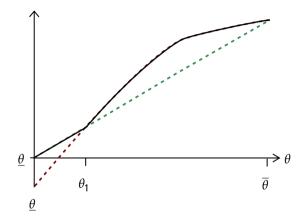

In practice, many government programs focused on goods consumed disproportionately by needy:

Examples:

- Egyptian *Tamween* food subsidy program subsidizes five loaves of *bαlαdi* bread/day at AUD 0.01/loaf, with a cap on weights and quality of bread.
- CalFresh Restaurant Meals Program subsidizes fast food restaurants not dine-in restaurants.
- Indonesian Fuel Subsidy Program subsidizes low-octane fuel (for motorbikes) and not high-octane fuel (for cars).
- \blacktriangleright Until $\sim\!\!2016$, Australia's Medicare subsidized amalgam fillings and not composite (tooth-coloured) fillings.

4(a) Increasing Motive for Redistribution

Suppose $\omega(\theta) \uparrow$ for each θ or, equivalently, $\alpha \downarrow$.

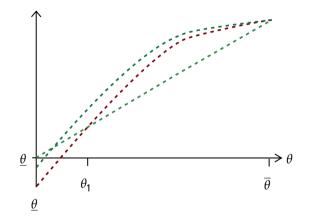

4(a) Increasing Motive for Redistribution

Suppose $\omega(\theta) \uparrow$ for each θ or, equivalently, $\alpha \downarrow$.

▶ virtual type $J(\theta)$ ↑

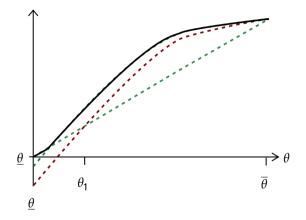

4(a) Increasing Motive for Redistribution

Suppose $\omega(\theta) \uparrow$ for each θ or, equivalently, $\alpha \downarrow$.

- ▶ virtual type $J(\theta)$ ↑
- \rightarrow each consumer's subsidy type $H(\theta) \uparrow$
- \rightarrow each consumer's allocation $q^*(\theta) \uparrow$
- → set of subsidized types ↑
- $\, \leadsto \,$ total subsidy per consumer \uparrow

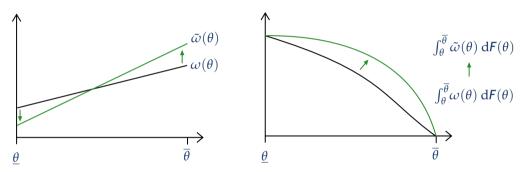

Planner & average eligible consumer prefer subsidies targeted to consumers with higher welfare weights.

4(b) Increasing Correlation

Suppose ω and θ become more correlated, in the sense of majorization \sim observe higher demand expect higher ω , i.e., for all $\theta \in \Theta$, $\mathbf{E}[\tilde{\omega}(\theta)|\theta \geq \hat{\theta}] \geq \mathbf{E}[\omega(\theta)|\theta \geq \hat{\theta}]$.

 \sim larger incentive to distort consumption \sim more generous subsidies.

Planner & average eligible consumer prefer subsidies for goods with more positive correlation between demand and welfare weights.

4(c) Decreasing Marginal Cost

Suppose marginal cost decreases $c \downarrow$ (equiv. demand increases, so $(v') \uparrow$).

No change in virtual type \sim no change in subsidy type.

- $\,\,\leadsto\,$ the set of subsidized types is unchanged, while
- ightsquigarrow each consumer's allocation $q^*(heta) \uparrow$
- \rightarrow total subsidy per subsidized consumer \uparrow .

4(c) Decreasing Marginal Cost

Suppose marginal cost decreases $c \downarrow$ (equiv. demand increases, so $(v') \uparrow$).

No change in virtual type \sim no change in subsidy type.

- $\,\,\leadsto\,$ the set of subsidized types is unchanged, while
- ightsquigarrow each consumer's allocation $q^*(heta) \uparrow$
- \rightarrow total subsidy per subsidized consumer \uparrow .

4(c) Decreasing Marginal Cost

Suppose marginal cost decreases $c \downarrow$ (equiv. demand increases, so $(v') \uparrow$).

No change in virtual type \sim no change in subsidy type.

- $\,\,\leadsto\,$ the set of subsidized types is unchanged, while
- ightarrow each consumer's allocation $q^*(\theta) \uparrow$
- \rightarrow total subsidy per subsidized consumer \uparrow .

Planner & average eligible consumer prefer subsidies for low cost / high demand goods.

Food Stamps (SNAP)

- Overview: U.S. program providing monthly food assistance to low-income individuals and families.
- ▶ Initial Support: Full subsidy up to a fixed dollar amount per month for eligible food items.
- Free Endowment: The subsidy starts as a full benefit and decreases after benefits are exhausted.
- Low Consumption Focus: Ensures a basic level of nutrition by covering initial consumption entirely.

Women, Infants, and Children (WIC)

- Overview: Nutritional assistance for low-income pregnant women, new mothers, and young children.
- ▶ Initial Support: Vouchers for essential foods like milk, eggs, baby formula.
- Free Endowment: Recipients get fully subsidized quantities of specific foods.
- ▶ Low Consumption Focus: Prioritizes providing a free minimum quantity of nutritious food to families.

Housing Choice Voucher Program (Section 8)

- Overview: subsidized housing assistance for low-income renters in the U.S.
- Initial Support: Covers a large portion of rent (up to 70%) for qualifying households.
- ► Free Endowment: A significant rent portion is initially fully subsidized.
- Low Consumption Focus: Ensures low-income renters pay only a small portion of their rent.

Lifeline Program

- Overview: U.S. program offering discounted phone and internet services to low-income households.
- ▶ Initial Support: Monthly discounts on basic telecommunication services.
- Free Endowment: Full subsidy of basic services for the most disadvantaged users.
- Low Consumption Focus: Provides essential access to communication services with high initial subsidies.

National School Lunch Program (NSLP)

- Overview: Provides free or reduced-price school meals for low-income students.
- ▶ Initial Support: Fully subsidized meals for eligible students based on family income.
- Free Endowment: Full meal subsidies provided for families below certain income thresholds.
- Low Consumption Focus: Ensures children receive at least one nutritious meal per day at no or low cost.

Australian Better Access Mental Health Initiative

- Overview: Australian government program subsidizing mental health services.
- ▶ Initial Subsidy: Up to 10 Medicare-subsidized sessions per year.
- Additional Support:
 - After initial sessions and doctor approval, become eligible for extra free/subsidized sessions.
 - Increased subsidy ensures access for those needing more care.

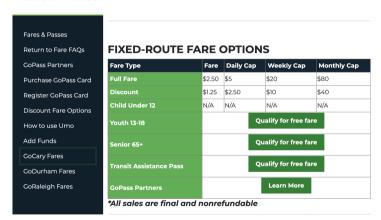

Australia's Child Care Subsidy (CCS)

- Overview: Government subsidy for childcare costs based on income and activity levels.
- Initial Subsidy: Covers a percentage of childcare fees up to a set number of hours.
- Additional Support:
 - Subsidy percentage increases as parents work, study, or volunteer more.
 - More hours of work/study lead to higher subsidies for additional childcare hours.
 - More children leads to higher subsidies per child.

Public Transit Fare Capping (Research Triangle, NC)

Fares & Passes

Other Cities With Similar Programs: New York, SF Bay Area, Portland, London, Dublin, Toronto, Vancouver, Los Angeles, Singapore, Sydney, Brisbane, Melbourne, Perth, Auckland.

Pharmaceutical Subsidy Programs: Australia, Norway, Sweden, Denmark

- Overview: Government programs reducing out-of-pocket medication costs.
- Australia (PBS): subsidizes prescription medicines; costs decrease after a yearly threshold (safety net) is reached.
- ► Helsenorge (Norway): Covers up to 90% of prescription costs after reaching an annual expenditure cap.
- Sweden: Once a patient reaches a yearly spending threshold, additional medications are free.
- **Denmark**: Progressive subsidy structure, with higher reimbursements as individual spending increases.

Cost-Sharing Reductions (CSRs) and Eligibility Limits

ACA Cost-Sharing Reductions (CSRs)

- What are CSRs?
 - Subsidies that lower out-of-pocket costs (e.g., co-pays, deductibles).
 - Available to individuals/families with incomes between 100% and 250% of the Federal Poverty Level (FPL).
- ► Eligibility Tied to Lower Insurance Plans
 - To qualify for CSRs, you must purchase a Silver-level plan on the ACA marketplace.
 - Other plan tiers (Bronze, Gold, or Platinum) do not offer CSRs, even if you're income-eligible.
 - Silver plans have a standard 70% actuarial value, but CSRs raise it to up to 94% for lower-income enrollees.
- Impact of Limiting to Silver Plans
 - Higher-income individuals may choose other plan levels, but lose CSR eligibility.
 - Lower-income enrollees are incentivized to choose Silver plans to reduce out-of-pocket costs.

German Health System: Prohibition of Topping Up

- ▶ Public Health Insurance: Citizens covered by statutory health insurance (SHI) cannot "top up" SHI with private insurance for services already covered.
- Supplementary Insurance: Private insurance can only be used for services not included in SHI (e.g., private rooms, certain dental services).
- Comprehensive Coverage: SHI already covers essential medical services, discouraging the need for topping up with private health plans.

Public Education: Prohibition of Private Tutoring in China & South Korea

- Public Education: Both China and South Korea provide universal public education for students, with restrictions on private supplementary tutoring.
- Prohibition: Private tutoring and after-school programs are heavily regulated or banned to prevent parents from "topping up" public education with private instruction.
- Equal Access: The aim is to reduce inequality in educational opportunities and prevent wealthier families from gaining an advantage through private education.

Public Housing

- Public Housing Programs: Residents in public housing receive heavily subsidized rent, often capped at a percentage of their income.
- Prohibition: Participants must choose between living in public housing or renting in the private market; they cannot "top up" their public housing subsidy to rent a private apartment.
- Example Cities and Countries:
 - Singapore: The Housing & Development Board (HDB) provides subsidized flats, and participants cannot receive additional subsidies to live in private housing.
 - Vienna, Austria: The city's extensive public housing program offers low-cost rental units, with no option to "top up" for private market rentals.
 - Hong Kong: The Public Rental Housing (PRH) program offers heavily subsidized apartments, and recipients must choose between public housing and private market rentals.

Egypt's Tamween Food Subsidy Program

- Overview: The Tamween program is one of the largest food subsidy systems in the world, providing essential goods to over 60 million Egyptians, mostly from low-income households.
- ► Targeted Subsidy:
 - Bread: Heavily subsidized at a fraction of market price (often less than 10% of the actual cost), making it affordable for the poor, who rely on it as a staple.
 - Other Essentials: Subsidies also cover rice, sugar, and cooking oil, basic items central to the diets of low-income families.
- **Exclusion:**
 - Meat and Dairy: These more expensive food items, consumed more frequently by wealthier households, are not subsidized. Consumers must pay market prices for these products.

Indonesian Fuel Subsidy Program: Pertamina

- Overview: Indonesia's fuel subsidy program supports transportation for low-income households.
- ► Targeted Subsidy: The program subsidizes low-octane fuel, which is primarily used by motorcycles, the preferred transport mode for poorer citizens.
- Exclusion: High-octane fuel, more commonly used by cars owned by wealthier households, is not subsidized.

CalFresh Restaurant Meals Program

- Overview: California's CalFresh program allows certain populations to use benefits for prepared meals.
- ► Targeted Subsidy: The program subsidizes meals, predominantly from fast food restaurants, providing affordable food options for homeless, elderly, and disabled individuals.
- **Exclusion**: Dine-in restaurants, typically frequented by wealthier individuals, are not included in the subsidy.

Public Dentistry Programs in Australia

- Overview: Australia's public dentistry programs provide dental care subsidies to low-income individuals.
- Targeted Subsidy: Prior to 2016, the program subsidized only amalgam fillings, a durable and cost-effective option used widely by lower-income patients.
- **Exclusion:** Composite (tooth-colored) fillings, which are more expensive and preferred by wealthier individuals, were not fully subsidized.
- Post-2016: amalgam fillings are being phased out due to mercury content.
